Introduction

Complex Networks

Complex network analysis is a collection of quantitative methods for studying the structure and dynamics of complex networked systems. Then, we focus on fundamental network analysis measures and algorithms related to node connectivity, distance, centrality, similarity and clustering.

Centralities

Subgraph Centrality in Complex Networks. We introduce a new centrality measure that characterizes the participation of each node in all subgraphs in a network. This measure is better able to discriminate the nodes of a network than alternate measures such as degree, closeness, betweenness and eigenvector centralities.

Community Detection

Community Detection in Complex Networks by Detecting and Expanding Core Nodes Through Extended Local Similarity of Nodes. First, a community's central node (core node) which has a high level of embeddedness is detected based on the similarity between graph's nodes.

Correlation

A complex network is said to be degree correlated if the degrees of nodes at the end of links occur together in a nonrandom manner. In a social network the nodes represent individuals, and the links between them conceptualize friendships or other social associations.

Similarity

Similarity of nodes is a basic structure quantification in complex networks. Then relative entropy is used to measure the difference between each pair of nodes' structural information. At last the value of relative entropy between each pair of nodes is used to measure nodes' structure similarity in complex networks.

Project-2

Centrality-Correlation Based Complex Network Similarity

The Proposed Approach is the following

Given a complex network of size n, and a set of k centrality measures $C = \{C_1, \ldots, C_k\}$, We compute for each centrality C_i the induced ranking vectors of the nodes σ^{n_i} . For each couple of centrality measures C_i , C_j we can compute the raking correlation factor $cor(\sigma^{n_i}, \sigma^{n_j})$. A network N_i can then be represented as a vector in the $k^*(k-1)/2$ dimensional space. Similarity between two networks N_i , N_j can then be measured as the inverse of the distance separating both networks is the new representation space. The goal of this project is to implement the proposed network similarity measure and to evaluate this approach by using this similarity measure to cluster networks generated using different network generators.

Creating a Random Networks

Generating random graph networks by using a function called **erdos.renyi.game** from **igraph package**.

```
s1 <- sample(100:5000,1) #randomly selecting RANGE S1 from 100 to 5000
s2 <- sample(150:5000,1) #Randomly selecting Range S2 from 150 to 5000
#creating a Random networks using erdos.renyi.game
g <- erdos.renyi.game(s1, s2, type = "gnm")</pre>
```

4 Calculating Centralities

Calculating Centralities (**Degree, Closeness, and Betweenness**) for each randomly generated graph by using **igraph package**.

```
#Calculating degree_centrality
degree_centrality <- degree(g, mode="all", normalized=T)

#Calculating closeness_centrality
closeness_cent <- closeness(g, mode="all", weights=NA, normalized=T)

#Calculating betweenness_centrality
betweenness_cent <- betweenness(g, directed = F, weights = NA, normalized = T)</pre>
```

Calculating Centrality Correlation

Calculating Centrality Correlation between the (**Degree, closeness, and Betweenness**) centralities using the function cor().

```
#Co-relation between the centralities to get X, Y, Z three point from whole network.

cor_1 <- cor(degree_centrality,closeness_cent, method = c("pearson", "kendall", "spearman"))

cor_2 <- cor(degree_centrality,betweenness_cent, method = c("pearson", "kendall", "spearman"))

cor_3 <- cor(closeness_cent,betweenness_cent, method = c("pearson", "kendall", "spearman"))
```

Creating a DataFrame

Creating a DataFrame from the Points occurred from **cor_1**, **cor_2** and **cor_3**. And removing unwanted columns.

```
#CREATING A DATAFRAME FROM LIST'S
data_frame <- ldply(graph_list, data.frame)
#removing unwanted data from DATA_FRAME
df = subset(data_frame, select = -c(.id))
#INFORLATION ABOUT DATA_FRAME WHICH IS CREATED FROM LIST'S X, Y, Z.
str(df)
dim(df)
summary(df)</pre>
```

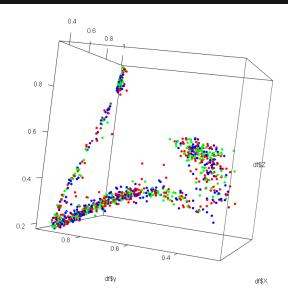

Results of DataFrame(df)

Here some of the results like Structure, Summary, Dimensions and Names in DataFrame.

```
data.frame':
                1000 obs. of 3 variables:
   X: num 0.395 0.484 0.78 0.404 0.439 ...

```

Plotting the DataFrame

```
#plotting from dataframe in 3D
plot3d(df$x,df$y,df$Z, col = c('red','green','blue'), size = 6)
```

♣ Standardization, where the dimensions now have a mean of zero

```
#mean of X
m_x <- mean(df$x)

#mean of Y
m_y <- mean(df$y)

#mean of Z
m_z <- mean(df$z)

x1 <- df$x - m_x
x1

#summary of X
summary(x1)

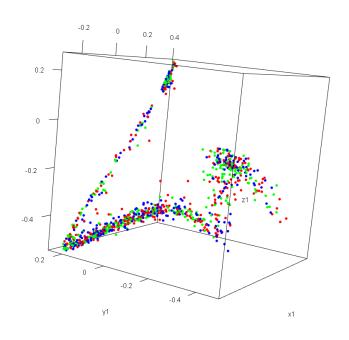

y1 <- df$y - m_y
y1

#summary of Y
summary(y1)

|
z1 <- df$z - m_y
z1

#summary of z
summary(z1)</pre>
```

```
#plotting from dataframe
plot3d(x1,y1,z1, col = c('red','green','blue'), size = 6)
```

Covariance matrix

Covariance measures how dimensions vary with respect to each other and the covariance matrix contains all covariance measures between all dimensions and Names in DataFrame and eigenvalues of the covariance matrix. An eigenvector is a direction and an eigenvalue is a number that indicates how much variance is in the data in that direction.

```
cv_xx <- cov(x1, x1)
cv_xy \leftarrow cov(x1, y1)
                                                                                           0.035516285
                                                                                                           0.0018181168
                                                                                                                           0.0330844490
cv_xz <- cov(x1, z1)
                                                                                           0.001818117 0.0485469935 -0.0005916369
0.033084449 -0.0005916369 0.0453420282
cv_yy <- cov(y1, y1)
          cov(y1, x1)
